

Full nomological network backbone

Adaptive edge pruning keeps the strongest global and local relationships while preserving every node in the full network.

Backbone view of the full pairwise S4 + S5 network. Statistics were calculated for all 1108 available unique pairs; this display keeps 197 adaptive-backbone edges: global $|r| \geq 0.35$, each node's 2 strongest ties, plus a maximum-spanning skeleton so all nodes remain visible. Node fill = type. N = 1,108.
